Key Information

HIV is a virus.

It cannot live for long outside of the body.

HIV can directly enter the body via the bloodstream, or mucous membranes such as:

vagina - via the lining of the vagina, cervix or womb

penis - via the urethra or inside of foreskin

anus - via the lining which is very delicate.

HIV enters and attacks the cells of the immune system itself - the very thing that would normally kill off a virus.

Once HIV is present in the body of an infected person, it can be found in their:

semen (cum) or pre-seminal fluid (pre-cum)

vaginal fluid

breast milk

blood (including menstrual blood).

rectal secretions/mucosa.

There are four main routes of HIV transmission:

unprotected vaginal or anal or oral sex (oral sex carries a very small risk)

sharing unsterilised injecting drug equipment

from mother-to-baby during pregnancy, birth or breastfeeding

infected blood transfusions or medical procedures, although most countries have processes in place to prevent this.

Who is at risk?

Anybody can be at risk of HIV if infected fluids of an HIV-positive person enters their body.

HIV does not only affect certain groups of people.

If people living with HIV are on antiretroviral treatment and have an undetectable viral load, the risk of HIV transmission is greatly reduced.

MYTHS!

HIV **cannot** be transmitted by:

Surfaces

Surfaces: HIV cannot be transmitted by contact with toilet seats, eating utensils, musical instruments, hugs or handshakes.

Insect bites

Insect bites: Insects such as mosquitoes don't transmit HIV because they do not inject blood when they bite.

Air

Air: Breathing the same air as someone living with HIV does not transmit HIV. Coughing, sneezing or spitting cannot transmit HIV either.

Sterile needles

Sterile needles: Sterilised or new needles and syringes are safe from HIV transmission. Do not share used needles.

Kissing

Kissing: Saliva contains very small amounts of HIV. The risk is negligible unless both partners have large open sores or bleeding gums.

Water

Water: HIV cannot survive in water, so you are free from HIV transmission in swimming pools, baths or shower areas.

FACTS!

HIV **can** be transmitted by:

Vaginal sex

Vaginal sex: HIV can be transmitted from woman to man or vice versa. Open cuts and sores increase the risk.

Anal sex

Anal sex: Higher risk than vaginal sex because the lining of the anus is more likely to tear, creating an entry point for HIV.

Oral sex

Oral sex: Has a very small risk, but only if there are sores in/around the mouth or on the receiving partner's genitals.

Injecting drugs

Injecting drugs: Shared unsterilised equipment can carry infected blood. Needles used for body piercing and tattooing can carry a small risk.

Blood transfusions

Blood transfusions: All donated blood should be tested for HIV; any untested blood carries a risk of transmission to the patient.

Mother-to-child

Mother-to-child: Transmission can occur during pregnancy, labour, delivery or breastfeeding if treatment is not taken routinely.
